

### FEATURES

- Low on resistance (300  $\Omega$  typical)
- Fast switching times
  - $t_{ON}$  250 ns maximum
  - $t_{OFF}$  250 ns maximum
- Low power dissipation (3.3 mW maximum)
- Fault and overvoltage protection ( $-40$  V to  $+55$  V)
- All switches off with power supply off
- Analog output of on channel clamped within power supplies if an overvoltage occurs
- Latch-up proof construction
- Break-before-make construction
- TTL and CMOS compatible inputs

### APPLICATIONS

- Existing multiplexer applications (both fault-protected and nonfault-protected)
- New designs requiring multiplexer functions

### GENERAL DESCRIPTION

The ADG508F, ADG509F, and ADG528F<sup>1</sup> are CMOS analog multiplexers, with the ADG508F and ADG528F comprising eight single channels and the ADG509F comprising four differential channels. These multiplexers provide fault protection. Using a series n-channel, p-channel, n-channel MOSFET structure, both device and signal source protection is provided in the event of an overvoltage or power loss. The multiplexer can withstand continuous overvoltage inputs from  $-40$  V to  $+55$  V. During fault conditions, the multiplexer input (or output) appears as an open circuit and only a few nanoamperes of leakage current will flow. This protects not only the multiplexer and the circuitry driven by the multiplexer, but also protects the sensors or signal sources that drive the multiplexer.

The ADG508F and ADG528F switch one of eight inputs to a common output as determined by the 3-bit binary address lines A0, A1, and A2. The ADG509F switches one of four differential inputs to a common differential output as determined by the 2-bit binary address lines A0 and A1. The ADG528F has on-chip address and control latches that facilitate microprocessor

### PRODUCT HIGHLIGHTS

1. Fault Protection.  
The ADG508F/ADG509F/ADG528F can withstand continuous voltage inputs from  $-40$  V to  $+55$  V. When a fault occurs due to the power supplies being turned off, all the channels are turned off and only a leakage current of a few nanoamperes flows.
2. On channel turns off while fault exists.
3. Low  $R_{ON}$ .
4. Fast switching times.
5. Break-before-make switching.  
Switches are guaranteed break-before-make so that input signals are protected against momentary shorting.
6. Trench isolation eliminates latch-up.  
A dielectric trench separates the p and n-channel MOSFETs thereby preventing latch-up.

**TIMING DIAGRAMS**

Figure 2 shows the timing sequence for latching the switch address and enable inputs. The latches are level sensitive; therefore, while  $\overline{WR}$  is held low, the latches are transparent and the switches respond to the address and enable inputs. This input data is latched on the rising edge of  $\overline{WR}$ .

Figure 3 shows the reset pulsewidth,  $t_{RS}$ , and the reset turnoff time,  $t_{OFF}(\overline{RS})$ . Note that all digital input signals rise and fall times are measured from 10% to 90% of 3 V.  $t_R = t_F = 20$  ns.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## THEORY OF OPERATION

The ADG508F/ADG509F/ADG528F multiplexers are capable of withstanding overvoltages from  $-40\text{ V}$  to  $+55\text{ V}$ , irrespective of whether the power supplies are present or not. Each channel of the multiplexer consists of an n-channel MOSFET, a p-channel MOSFET, and an n-channel MOSFET, connected in series. When the analog input exceeds the power supplies, one of the MOSFETs will switch off, limiting the current to submicroamp levels, thereby preventing the overvoltage from damaging any circuitry following the multiplexer. Figure 17 illustrates the channel architecture that enables these multiplexers to withstand continuous overvoltages.

When an analog input of  $V_{SS} + 3\text{ V}$  to  $V_{DD} - 1.5\text{ V}$  is applied to the ADG508F/ADG509F/ADG528F, the multiplexer behaves as a standard multiplexer, with specifications similar to a standard multiplexer, for example, the on-resistance is  $400\ \Omega$  maximum. However, when an overvoltage is applied to the device, one of the three MOSFETs will turn off.

Figure 17 to Figure 20 show the conditions of the three MOSFETs for the various overvoltage situations. When the analog input applied to an ON channel approaches the positive power supply line, the n-channel MOSFET turns OFF since the voltage on the analog input exceeds the difference between  $V_{DD}$  and the n-channel threshold voltage ( $V_{TN}$ ). When a voltage more negative than  $V_{SS}$  is applied to the multiplexer, the p-channel MOSFET will turn off since the analog input is more negative than the difference between  $V_{SS}$  and the p-channel threshold voltage ( $V_{TP}$ ). Since  $V_{TN}$  is nominally  $1.5\text{ V}$  and  $V_{TP}$  is typically  $3\text{ V}$ , the analog input range to the multiplexer is limited to  $-12\text{ V}$  to  $+13.5\text{ V}$  when a  $\pm 15\text{ V}$  power supply is used.

When the power supplies are present but the channel is off, again either the p-channel MOSFET or one of the n-channel MOSFETs will turn off when an overvoltage occurs.

Finally, when the power supplies are off, the gate of each MOSFET will be at ground. A negative overvoltage switches on the first n-channel MOSFET but the bias produced by the overvoltage causes the p-channel MOSFET to remain turned off. With a positive overvoltage, the first MOSFET in the series will remain off since the gate to source voltage applied to this MOSFET is negative.

During fault conditions, the leakage current into and out of the ADG508F/ADG509F/ADG528F is limited to a few microamps. This protects the multiplexer and succeeding circuitry from over stresses as well as protecting the signal sources which drive the multiplexer. Also, the other channels of the multiplexer will be undisturbed by the overvoltage and will continue to operate normally.
