SBAS040A – JUNE 2001

10-Bit, 40MHz Sampling ANALOG-TO-DIGITAL CONVERTER

FEATURES

- NO MISSING CODES
- INTERNAL REFERENCE
- LOW POWER: 380mW
- HIGH SNR: 58dB
- INTERNAL TRACK-AND-HOLD
- PACKAGES: SO-28 and SSOP-28

APPLICATIONS

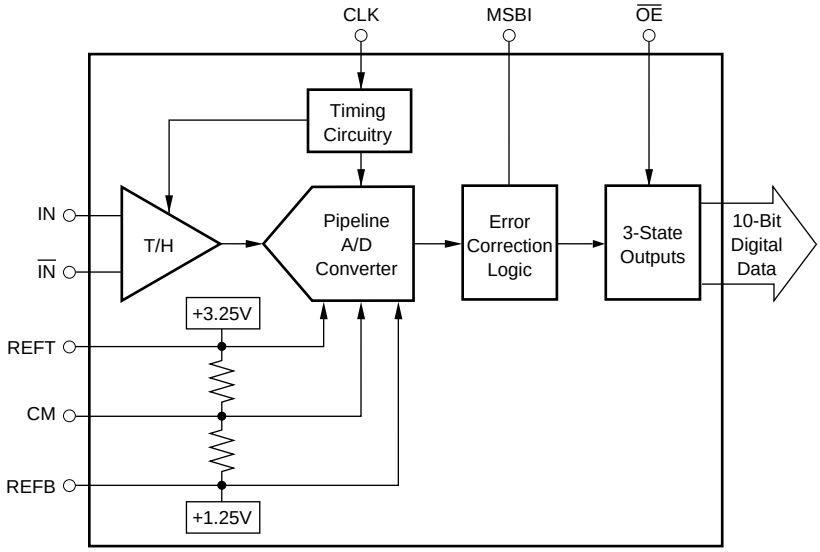
- VIDEO DIGITIZING
- ULTRASOUND IMAGING
- GAMMA CAMERAS
- SET-TOP BOXES
- CABLE MODEMS
- CCD IMAGING
  - Color Copiers
  - Scanners
  - Camcorders
  - Security Cameras
  - Fax Machines
- IF AND BASEBAND DIGITIZATION
- TEST INSTRUMENTATION

DESCRIPTION

The ADS821 is a low-power, monolithic 10-bit, 40MHz Analog-to-Digital (A/D) converter utilizing a small geometry CMOS process. This complete converter includes a 10-bit quantizer with internal track-and-hold, reference, and a power down feature. It operates from a single +5V power supply and can be configured to accept either differential or single-ended input signals.

The ADS821 employs digital error correction to provide excellent Nyquist differential linearity performance for demanding imaging applications. Its low distortion, high SNR, and high oversampling capability give it the extra margin needed for telecommunications and video applications.

This high-performance converter is specified for ac and DC performance at a 40MHz sampling rate. The ADS821 is available in SO-28 and SSOP-28 packages.



Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

ABSOLUTE MAXIMUM RATINGS[1]

$+V_S$	+6V
Analog Input	0V to ($+V_S$ + 300mV)
Logic Input	0V to ($+V_S$ + 300mV)
Case Temperature	+100°C
Junction Temperature	+150°C
Storage Temperature	+125°C
External Top Reference Voltage (REFT)	+3.4V max
External Bottom Reference Voltage (REFB)	+1.1V min

NOTE: (1) Stresses above these ratings may permanently damage the device.

ELECTROSTATIC DISCHARGE SENSITIVITY

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

PACKAGE/ORDERING INFORMATION

PRODUCT	PACKAGE	PACKAGE DRAWING NUMBER	SPECIFIED TEMPERATURE RANGE	PACKAGE MARKING	ORDERING NUMBER[1]	TRANSPORT MEDIA
ADS821U	SO-28	217	–40°C to +85°C	ADS821U	ADS821U	Rails
ADS821E	SSOP-28	324	–40°C to +85°C	ADS821E	ADS821E	Rails
ADS821E	SSOP-28	324	–40°C to +85°C	ADS821E	ADS821E/1K	Tape and Reel

NOTE: (1) Models with a slash (/) are available only in Tape and Reel in the quantities indicated (e.g., /1K indicates 1000 devices per reel). Ordering 1000 pieces of "ADS821E/1K" will get a single 1000-piece Tape and Reel.

ELECTRICAL CHARACTERISTICS

At T_A = +25°C, V_S = +5V, Sampling Rate = 40MHz, with a 50% duty cycle clock having a 2ns rise-and-fall time, unless otherwise noted.

THEORY OF OPERATION

The ADS821 is a high-speed, sampling A/D converter with pipelining. It uses a fully differential architecture and digital error correction to guarantee 10-bit resolution. The differential track-and-hold circuit is shown in Figure 1. The switches are controlled by an internal clock that has a non-overlapping two-phase signal, $\phi 1$ and $\phi 2$. At the sampling time, the input signal is sampled on the bottom plates of the input capacitors. In the next clock phase, $\phi 2$, the bottom plates of the input capacitors are connected together and the feedback capacitors are switched to the op-amp output. At this time, the charge redistributes between C_I and C_H, completing one track-and-hold cycle. The differential output is a held DC representation of the analog input at the sample time. The track-and-hold circuit can also convert a single-ended input signal into a fully differential signal for the quantizer.

The pipelined quantizer architecture has 9 stages with each stage containing a two-bit quantizer and a two bit digital-to-analog converter, as shown in Figure 2. Each two-bit quantizer stage converts on the edge of the sub-clock, which is twice the frequency of the externally applied clock. The output of each quantizer is fed into its own delay line to

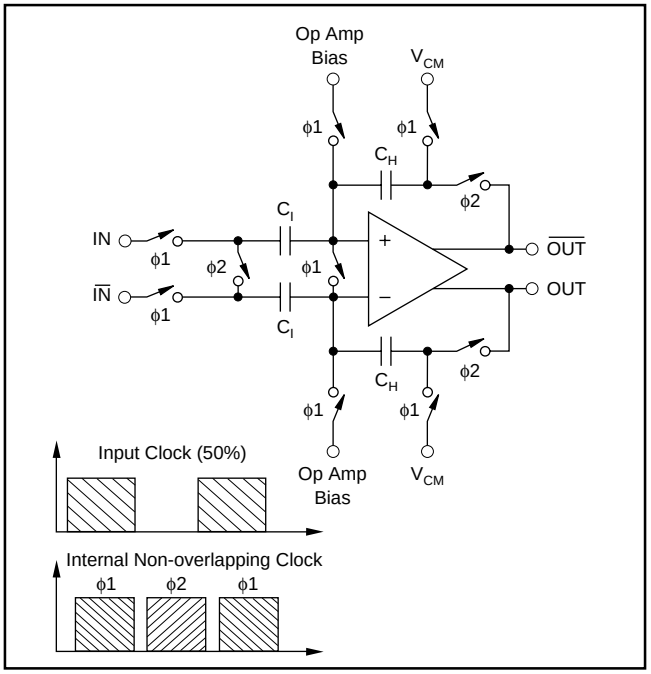

FIGURE 1. Input Track-and-Hold Configuration with Timing Signals.

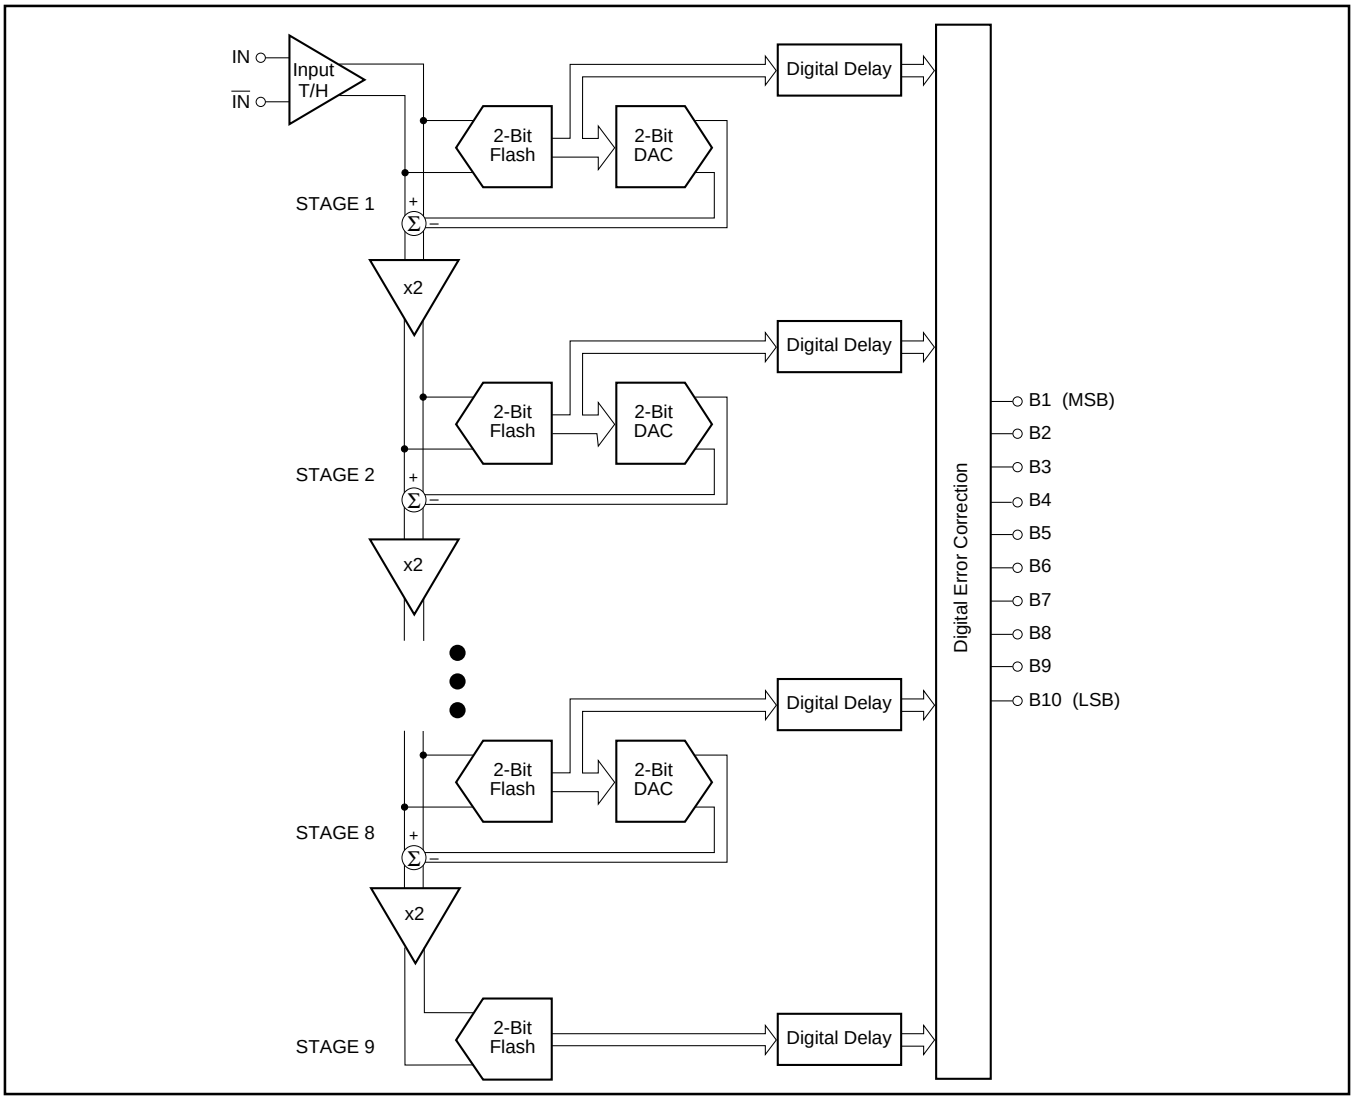

FIGURE 2. Pipeline A/D Converter Architecture.

time-align it with the data created from the following quantizer stages. This aligned data is fed into a digital error correction circuit that can adjust the output data based on the information found on the redundant bits. This technique gives the ADS821 excellent differential linearity and guarantees no missing codes at the 10-bit level.

The output data is available in Straight Offset Binary (SOB) or Binary Two's Complement (BTC) format.

THE ANALOG INPUT AND INTERNAL REFERENCE

The analog input of the ADS821 can be configured in various ways and driven with different circuits, depending on the nature of the signal and the level of performance desired. The ADS821 has an internal reference that sets the full-scale input range of the A/D converter. The differential input range has each input centered around the common-mode of +2.25V, with each of the two inputs having a full-scale range of +1.25V to +3.25V. Since each input is 2Vp-p and 180° out-of-phase with the other, a 4V differential input signal to the quantizer results. As shown in Figure 3, the positive full-scale reference (REFT) and the negative full-scale reference (REFB) are brought out for external bypassing. In addition, the common-mode voltage (CM) may be used as a reference to provide the appropriate offset for the driving circuitry. However, care must be taken not to appreciably load this reference node. For more information regarding external references, single-ended inputs, and ADS821 drive circuits, refer to the applications section.

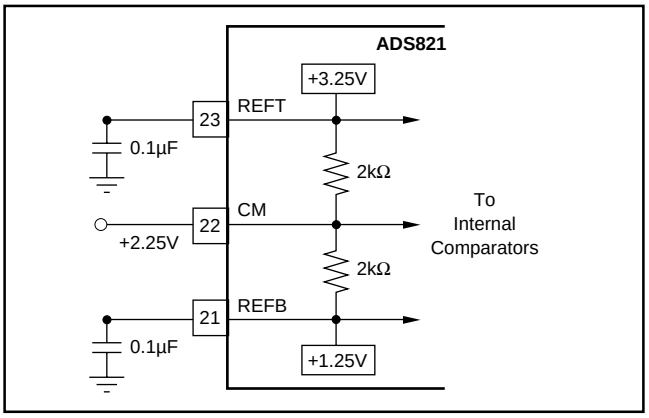

FIGURE 3. Internal Reference Structure.

CLOCK REQUIREMENTS

The CLK pin accepts a CMOS level clock input. Both the rising and falling edges of the externally applied clock controls the various interstage conversions in the pipeline. Therefore, the clock signal's jitter, rise-and-fall times and duty cycle can affect conversion performance.

- Low clock **jitter** is critical to SNR performance in frequency-domain signal environments.
- Clock **rise and fall times** should be as short as possible (< 2ns for best performance).
- For most applications, the clock duty should be set to 50%. However, for applications requiring no missing codes, a slight skew in the duty cycle will improve DNL performance for conversion rates > 35MHz and input frequencies < 2MHz (see Timing Diagram) in the SO package. For the best performance in the SSOP package, the clock should be skewed under all input frequencies with conversion rates > 35MHz. A possible method for skewing the 50% duty cycle source is shown in Figure 4.

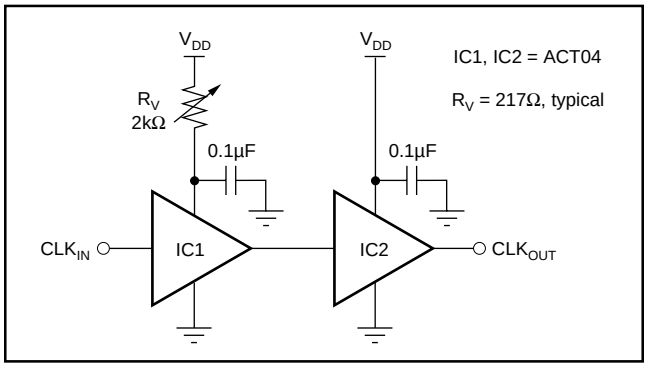

FIGURE 4. Clock Skew Circuit.

DIGITAL OUTPUT DATA

The 10-bit output data is provided at CMOS logic levels. There is a 6.5 clock cycle data latency from the start convert signal to the valid output data. The standard output coding is Straight Offset Binary where a full-scale input signal corresponds to all "1's" at the output. This condition is met with pin 19 LOW or Floating due to an internal pull-down resistor. By applying a high voltage to this pin, a Binary Two's Complement output will be provided where the most significant bit is inverted. The digital outputs of the ADS821 can be set to a high impedance state by driving $\overline{OE}$ (pin 18) with a logic HIGH. Normal operation is achieved with pin 18 LOW or Floating due to internal pull-down resistors. This function is provided for testability purposes and is not meant to drive digital buses directly or be dynamically changed during the conversion process.

	OUTPUT CODE	
DIFFERENTIAL INPUT[1]	SOB PIN 19 FLOATING or LOW	BTC PIN 19 HIGH
+FS (IN = +3.25V, $\overline{IN}$ = +1.25V)	1111111111	0111111111

Note: In the single-ended input mode, +FS = +4.25V and –FS = +0.25V.		

TABLE I. Coding Table for the ADS821.

APPLICATIONS

DRIVING THE ADS821

The ADS821 has a differential input with a common-mode of +2.25V. For ac-coupled applications, the simplest way to create this differential input is to drive the primary winding of a transformer with a single-ended input. A differential output is created on the secondary if the center tap is tied to the common-mode voltage (CM) of +2.25V, as per Figure 5. This transformer-coupled input arrangement provides good high frequency ac performance. It is important to select a transformer that gives low distortion and does not exhibit core saturation at full-scale voltage levels. Since the transformer does not appreciably load the ladder, there is no need to buffer the common-mode (CM) output in this instance. In general, it is advisable to keep the current draw from the CM output pin below 0.5µA to avoid nonlinearity in the internal reference ladder. A FET input operational amplifier such as the OPA130 can provide a buffered reference for driving external circuitry. The analog IN and $\overline{IN}$ inputs should be bypassed with 22pF capacitors to minimize track-and-hold glitches and to improve high input frequency performance.

Figure 6 shows an ac-coupled single-ended input interface circuit using the low-cost, current feedback OPA658 as the active gain stage. When testing this configuration in gains of +4, +5.8, and +8.2, it was noted that reducing the feedback resistor of the OPA658 from the typical 402Ω to 360Ω resulted in a wider bandwidth, thus improving distortion at higher gains. The gain resistor was scaled to 120Ω, 75Ω, and 50Ω for each of the three gain settings. The two 330Ω resistors set the RC time constant and the values can be varied, although higher values will have the effect of moving the corner frequency of the created high-pass filter down. In Figure 6, the –3dB point is set at 4.2kHz.

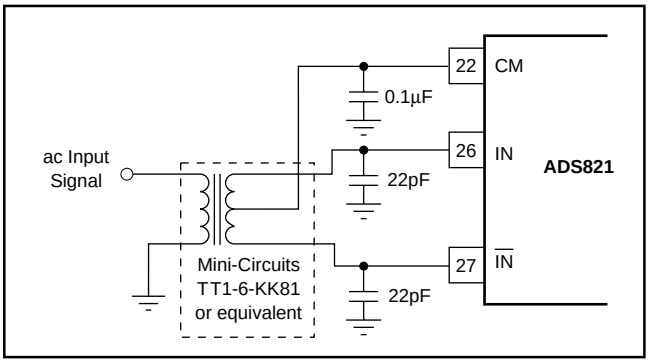

FIGURE 5. AC-Coupled Single-Ended to Differential Drive Circuit Using a Transformer.

Figure 7 illustrates another possible low-cost interface circuit that utilizes resistors and capacitors in place of a transformer. Depending on the signal bandwidth, the component values should be carefully selected in order to maintain the performance outlined in the data sheet. The input capacitors, C_{IN}, and the input resistors, R_{IN}, create a high-pass filter with the lower corner frequency at $f_C = 1/(2\pi R_{IN}C_{IN})$. The corner frequency can be reduced by either increasing the value of R_{IN} or C_{IN}. If the circuit operates with a 50Ω or 75Ω impedance level, the resistors are fixed and only the value of the capacitor can be increased. Usually ac-coupling capacitors are electrolytic or tantalum capacitors with values of 1µF or higher. It should be noted that these large capacitors become inductive with increased input frequency, which could lead to signal amplitude errors or oscillation. To maintain a low ac-coupling impedance throughout the signal band, a small value (e.g. 1µF) ceramic capacitor could be added in parallel with the polarized capacitor.

Capacitors C_{SH1} and C_{SH2} are used to minimize current glitches resulting from the switching in the input track-and-hold stage and to improve signal-to-noise performance. These capacitors can also be used to establish a low-pass filter and effectively reduce the noise bandwidth. In order to create a real pole, resistors R_{SER1} and R_{SER2} were added in series with each input. The cut-off frequency of the filter is determined by $f_C = 1/(2\pi R_{SER} \bullet (C_{SH}+C_{ADC}))$ where R_{SER} is the resistor in series with the input, C_{SH} is the external capacitor from the input to ground, and C_{ADC} is the internal input capacitance of the A/D converter (typically 4pF).

Resistors R_1 and R_2 are used to derive the necessary common-mode voltage from the buffered top and bottom references.

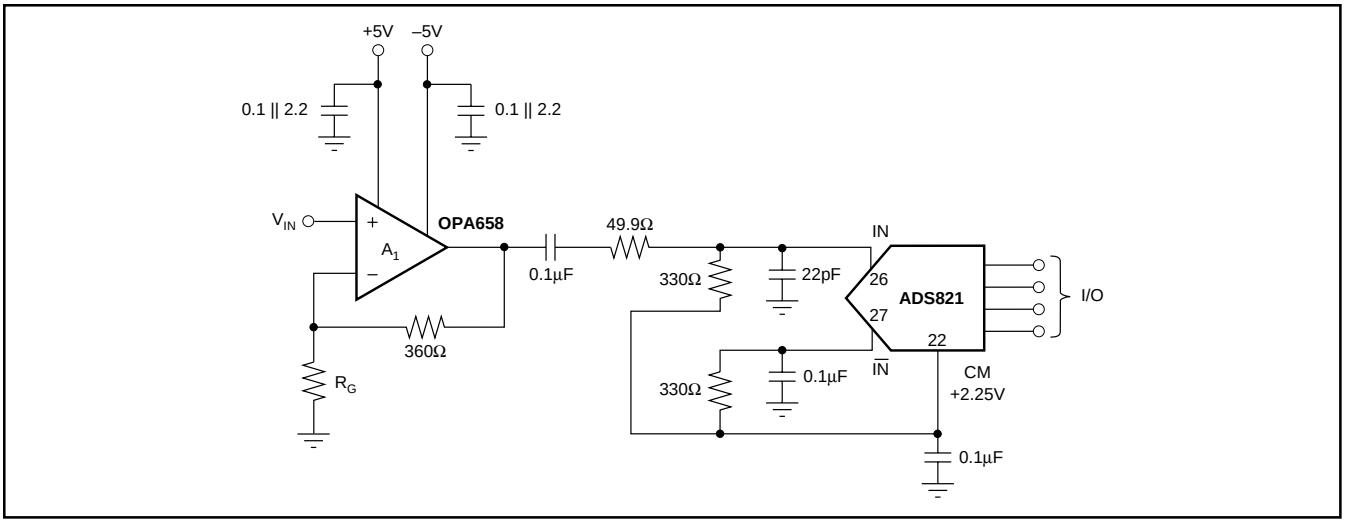

FIGURE 6. Low-Cost, AC-Coupled, Single-Ended Input Circuit.

The total load of the resistor string should be selected so that the current does not exceed 1mA. Although the circuit in Figure 7 uses two resistors of equal value so that the common-mode voltage is centered between the top and bottom reference (+2.25V), it is not necessary to do so. In all cases the center point, V_{CM}, should be bypassed to ground in order to provide a low impedance ac ground.

If the signal needs to be DC coupled to the input of the ADS821, an operational amplifier input circuit is required. In the differential input mode, any single-ended signal must be modified to create a differential signal. This can be accomplished by using two operational amplifiers, one in the noninverting mode for the input and the other amplifier in the inverting mode for the complementary input. The low distortion circuit in Figure 8 will provide the necessary input shifting required for signals centered around ground. It also employs a diode for output level shifting to guarantee a low distortion +3.25V output swing. See Figure 9 for another DC-coupled circuit. Other amplifiers can be used in place of the OPA642s if the lowest distortion is not necessary. If output level shifting circuits are not used, care must be taken to select operational amplifiers that give the necessary performance when swinging to +3.25V with a ±5V supply operational amplifier. The OPA620 and OPA621, or the lower power OPA650 or OPA651 can be used in place of the OPA642s in Figure 8. In that configuration, the OPA650 and OPA651 will typically swing to within 100mV of positive full scale. If the OPA621 or OPA651 is used, the input buffer must be configured in a gain of 2.

The ADS821 can also be configured with a single-ended input full-scale range of +0.25V to +4.25V by tying the complementary input to the common-mode reference voltage, see Figure 10. This configuration will result in increased even-order harmonics, especially at higher input frequencies. However, this tradeoff may be quite acceptable for time-domain applications. The driving amplifier must give adequate performance with a +0.25V to +4.25V output swing in this case.

EXTERNAL REFERENCES AND ADJUSTMENT OF FULL-SCALE RANGE

The internal reference buffers are limited to approximately 1mA of output current. As a result, these internal +1.25V and +3.25V references may be overridden by external references that have at least 18mA (at room temperature) of output drive capability. In this instance, the common-mode voltage will be set halfway between the two references. This feature can be used to adjust the gain error, improve gain drift, or to change the full-scale input range of the ADS821. Changing the full-scale range to a lower value has the benefit of easing the swing requirements of external input amplifiers. The external references can vary as long as the value of the external top reference ($REFT_{EXT}$) is less than or equal to +3.4V, the value of the external bottom reference ($REFB_{EXT}$) is greater than or equal to +1.1V, and the difference between the external references are greater than or equal to 800mV.

For the differential configuration, the full-scale input range will be set to the external reference values that are selected. For the single-ended mode, the input range is $2 \bullet (REFT_{EXT} - REFB_{EXT})$, with the common-mode being centered at $(REFT_{EXT} + REFB_{EXT})/2$. Refer to the typical performance curves for expected performance versus full-scale input range.

The circuit in Figure 11 works completely on a single +5V supply. As a reference element, it uses the micro-power reference REF1004-2.5, which is set to a quiescent current of 0.1mA. Amplifier A_2 is configured as a follower to buffer the +1.25V generated from the resistor divider. To provide the necessary current drive, a pull-down resistor (R_P) is added.

Amplifier A_1 is configured as an adjustable gain stage, with a range of approximately 1 to 1.32. The pull-up resistor again relieves the op amp from providing the full current drive. The value of the pull-up, pull-down resistors is not critical and can be varied to optimize power consumption. The need for pull-up, pull-down resistors depends only on the drive capability of the selected drive amplifier and thus can be omitted.

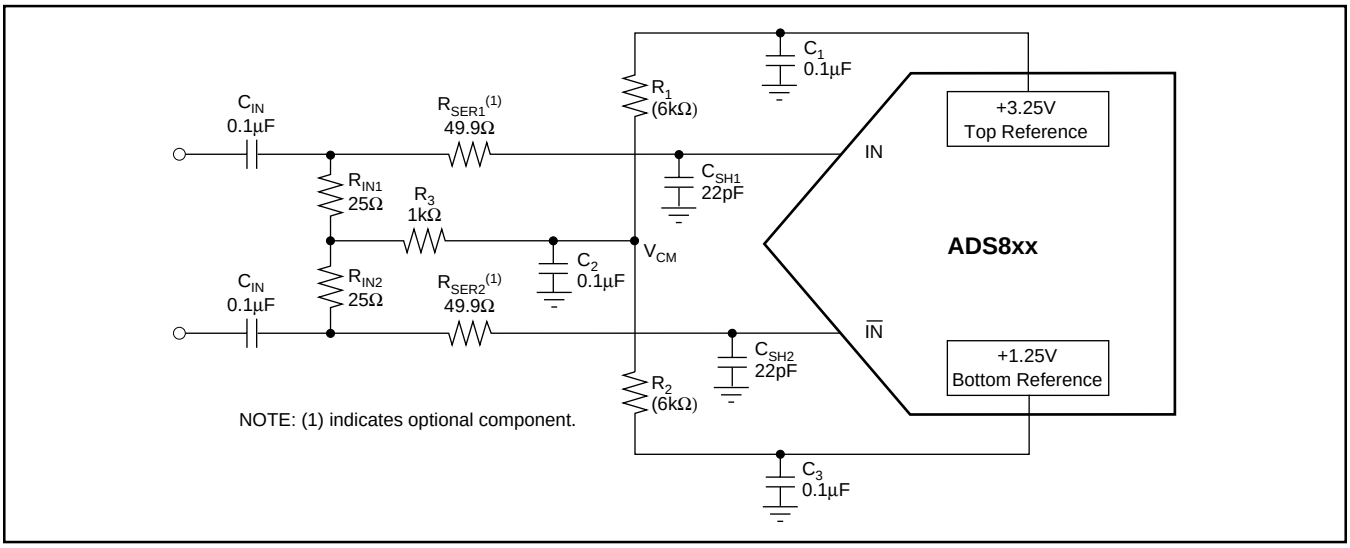

FIGURE 7. AC-Coupled Differential Input Circuit.

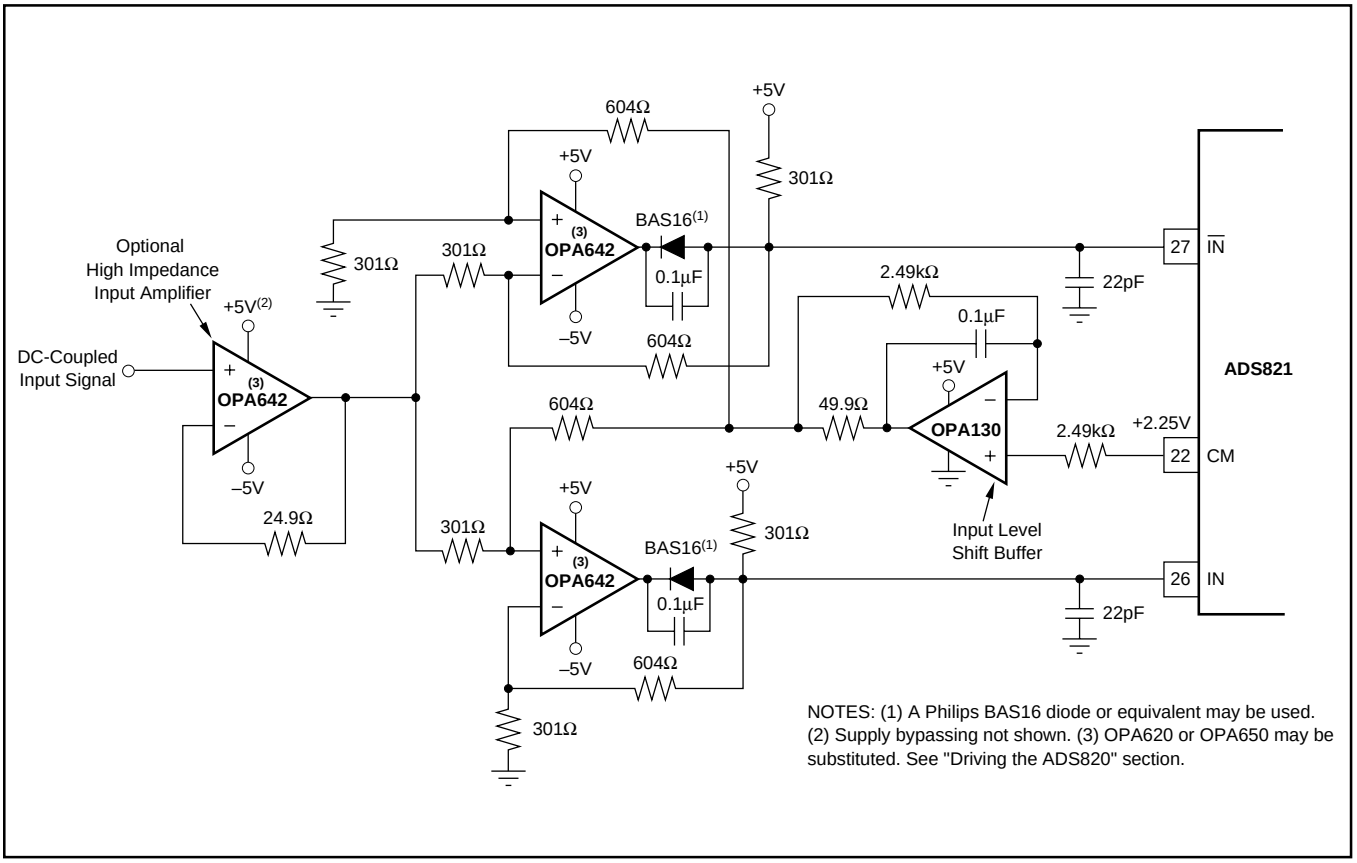

FIGURE 8. A Low Distortion DC-Coupled, Single-Ended to Differential Input Driver Circuit.

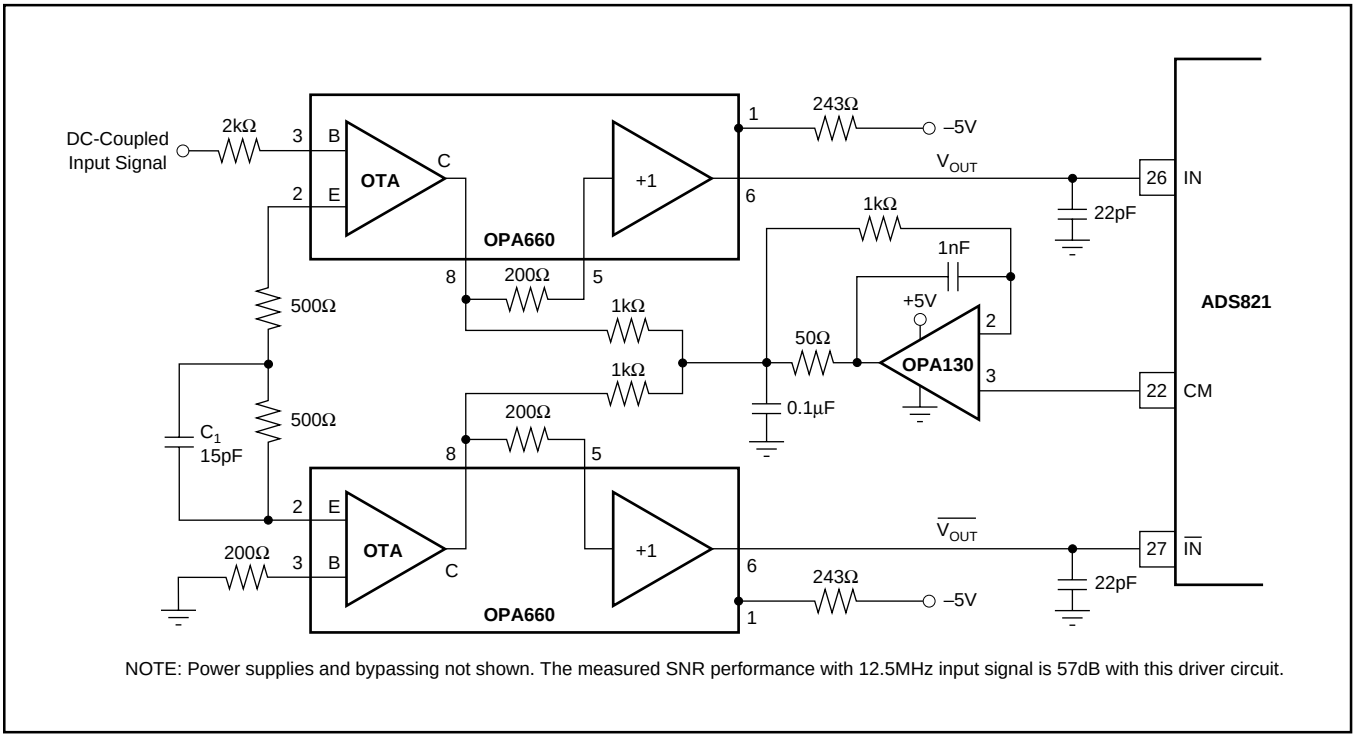

NOTE: Power supplies and bypassing not shown. The measured SNR performance with 12.5MHz input signal is 57dB with this driver circuit.

FIGURE 9. A Wideband DC-Coupled, Single-Ended to Differential Input Driver Circuit.

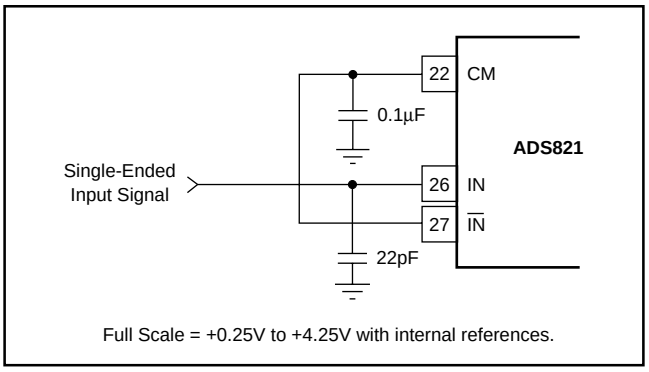

FIGURE 10. Single-Ended Input Connection.

PC-BOARD LAYOUT AND BYPASSING

A well-designed, clean pc-board layout will assure proper operation and clean spectral response. Proper grounding and bypassing, short lead lengths, and the use of ground planes are particularly important for high-frequency circuits. Multilayer pc-boards are recommended for best performance but if carefully designed, a two-sided pc-board with large, heavy ground planes can give excellent results. It is recommended that the analog and digital ground pins of the ADS821 be connected directly to the analog ground plane. In our experience, this gives the most consistent results. The A/D converter power-supply commons should be tied together at the analog ground plane. Power supplies should be bypassed with 0.1µF ceramic capacitors as close to the pin as possible.

DYNAMIC PERFORMANCE TESTING

The ADS821 is a high performance converter and careful attention to test techniques is necessary to achieve accurate results. Highly accurate phase-locked signal sources allow high resolution FFT measurements to be made without using data windowing functions. A low jitter signal generator, such as the HP8644A for the test signal, phase-locked with a low jitter HP8022A pulse generator for the A/D converter clock, gives excellent results. Low-pass filtering (or bandpass filtering) of test signals is absolutely necessary to test the low distortion of the ADS821. Using a signal amplitude slightly lower than full scale will allow a small amount of "headroom" so that noise or DC offset voltage will not overrange the A/D converter and cause clipping on signal peaks.

DYNAMIC PERFORMANCE DEFINITIONS

1. Signal-to-Noise-and-Distortion Ratio (SINAD):

$$10 \log \frac{\text{Sinewave Signal Power}}{\text{Noise + Harmonic Power (first 15 harmonics)}}$$

2. Signal-to-Noise Ratio (SNR):

$$10 \log \frac{\text{Sinewave Signal Power}}{\text{Noise Power}}$$

3. Intermodulation Distortion (IMD):

$$10 \log \frac{\text{Highest IMD Product Power (to } 5^{th} \text{ order)}}{\text{Sinewave Signal Power}}$$

IMD is referenced to the larger of the test signals f_1 or f_2. Five "bins" either side of peak are used for calculation of fundamental and harmonic power. The "0" frequency bin (DC) is not included in these calculations as it is of little importance in dynamic signal processing applications.

PACKAGING INFORMATION

ORDERABLE DEVICE	STATUS(1)	PACKAGE TYPE	PACKAGE DRAWING	PINS	PACKAGE QTY
ADS821E	OBSOLETE	SSOP	DB	28	
ADS821E/1K	OBSOLETE	SSOP	DB	28	
ADS821U	ACTIVE	SOIC	DW	28	28

(1) The marketing status values are defined as follows:
ACTIVE: Product device recommended for new designs.
LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.
NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.
PREVIEW: Device has been announced but is not in production. Samples may or may not be available.
OBSOLETE: TI has discontinued the production of the device.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.
