

High Bandwidth, Fast Fault Response Current Sensor IC In Thermally Enhanced Package

Features and Benefits

- Industry-leading noise performance with 120 kHz bandwidth through proprietary amplifier and filter design techniques
- Integrated shield greatly reduces capacitive coupling from current conductor to die due to high dV/dt, and prevents offset drift in high-side applications
- Small footprint surface mount QSOP24 package
- 2100 V_{RMS} isolation voltage between primary current path and sensor IC electronics
- 1.1 mΩ primary conductor resistance for low power loss
- User-settable Overcurrent Fault level
- Overcurrent Fault signal typically responds to an overcurrent condition in < 2 μs
- Filter pin capacitor sets analog signal bandwidth
- ±2% typical output error
- 3 to 5.5 V, single supply operation
- Factory trimmed sensitivity, quiescent output voltage, and associated temperature coefficients
- Chopper stabilization results in extremely stable quiescent output voltage
- Ratiometric output from supply voltage

Package: 24 pin QSOP (suffix LF)

Description

The Allegro® ACS709 current sensor IC provides economical and precise means for current sensing applications in industrial, automotive, commercial, and communications systems. The device is offered in a small footprint surface mount package that allows easy implementation in customer applications.

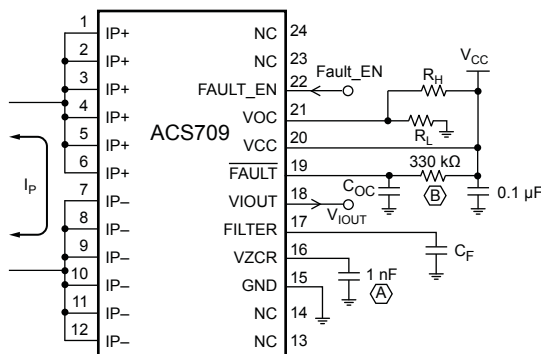

The ACS709 consists of a precision linear Hall sensor integrated circuit with a copper conduction path located near the surface of the silicon die. Applied current flows through the copper conduction path, and the analog output voltage from the Hall sensor IC linearly tracks the magnetic field generated by the applied current. The accuracy of the ACS709 is maximized with this patented packaging configuration because the Hall element is situated in extremely close proximity to the current to be measured.

High level immunity to current conductor dV/dt and stray electric fields, offered by Allegro proprietary integrated shield technology, guarantees low output ripple and low offset drift in high-side applications.

The voltage on the Overcurrent Input (VOC pin) allows customers to define an overcurrent fault threshold for the device. When the current flowing through the copper conduction path (between the IP+ and IP- pins) exceeds this threshold,

Typical Application

| | |
|------------|---|
| R_H, R_L | Sets resistor divider reference for V_{OC} |
| C_F | Noise and bandwidth limiting filter capacitor |
| C_{OC} | Fault delay setting capacitor, 22 nF maximum |
| (A) | Use of capacitor required |
| (B) | Use of resistor optional |

ACS709

High Bandwidth, Fast Fault Response Current Sensor IC In Thermally Enhanced Package

Description (continued)

the open drain Overcurrent Fault pin will transition to a logic low state. Factory programming of the linear Hall sensor IC inside of the ACS709 results in exceptional accuracy in both analog and digital output signals.

The internal resistance of the copper path used for current sensing is typically 1.1 mΩ, for low power loss. Also, the current conduction path is electrically isolated from the low voltage device inputs and

outputs. This allows the ACS709 family of sensor ICs to be used in applications requiring electrical isolation, without the use of opto-isolators or other costly isolation techniques.

Applications include:

- Motor control and protection
- Load management and overcurrent detection
- Power conversion and battery monitoring / UPS systems

Selection Guide

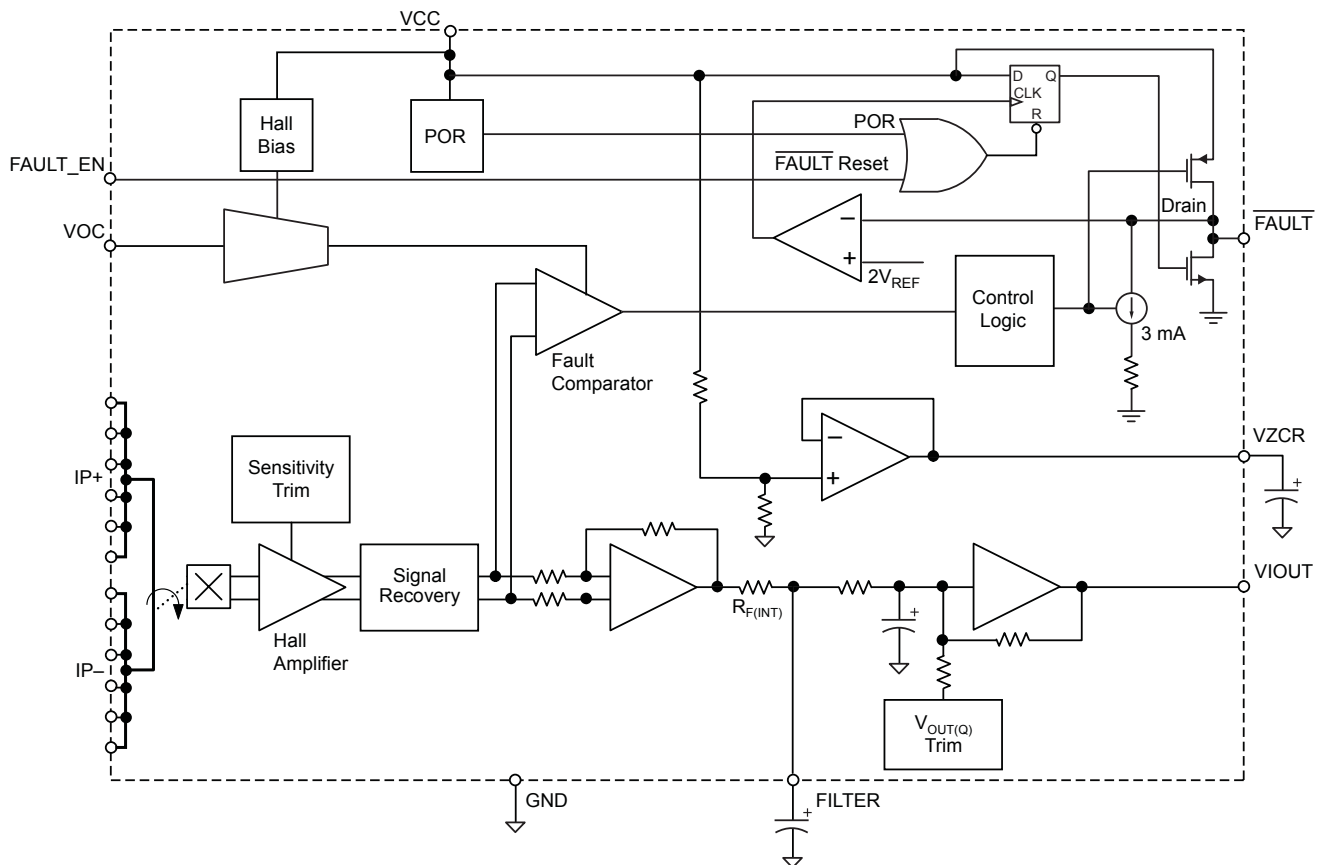

| Part Number | $I_{P(LIN)}$ (A) | Sens (Typ at $V_{CC} = 5\text{ V}$) (mV/A) | T_A (°C) | Packing* |
|--------------------|---------------------|---|---------------|-------------------------------------|
| ACS709LLFTR-35BB-T | 75 | 28 | -40 to 150 | Tape and Reel, 2500 pieces per reel |
| ACS709LLFTR-20BB-T | 37.5 | 56 | | |

*Contact Allegro for packing options.

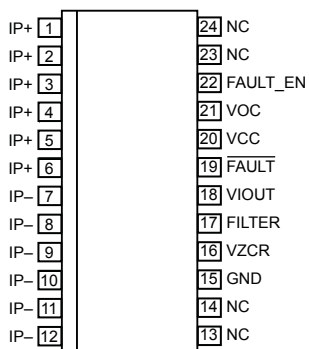

Absolute Maximum Ratings

| Characteristic | Symbol | Notes | Rating | Units |
|--|------------------------|---|------------|-------|
| Supply Voltage | V_{CC} | | 8 | V |
| Filter Pin | V_{FILTER} | | 8 | V |
| Analog Output Pin | V_{IOUT} | | 32 | V |
| Overcurrent Input Pin | V_{OC} | | 8 | V |
| Overcurrent \overline{FAULT} Pin | $V_{\overline{FAULT}}$ | | 8 | V |
| Fault Enable (FAULT_EN) Pin | $V_{FAULTEN}$ | | 8 | V |
| Voltage Reference Output Pin | V_{ZCR} | | 8 | V |
| DC Reverse Voltage: Supply Voltage, Filter, Analog Output, Overcurrent Input, Overcurrent Fault, Fault Enable, and Voltage Reference Output Pins | V_{Rdcx} | | -0.5 | V |
| Isolation Voltage | V_{ISO} | 60 Hz AC, $T_A = 25^\circ\text{C}$, 1 minute | 2100 | VAC |
| Output Current Source | $I_{IOUT(SOURCE)}$ | | 3 | mA |
| Output Current Sink | $I_{IOUT(SINK)}$ | | 1 | mA |
| Operating Ambient Temperature | T_A | Range L | -40 to 150 | °C |
| Junction Temperature | $T_J(\text{max})$ | | 165 | °C |
| Storage Temperature | T_{stg} | | -65 to 170 | °C |

Pin-out Diagram

Terminal List Table

| Number | Name | Description |
|----------------|----------|---|
| 1 through 6 | IP+ | Sensed current copper conduction path pins. Terminals for current being sensed; fused internally, loop to IP- pins; unidirectional or bidirectional current flow. |
| 7 through 12 | IP- | Sensed current copper conduction path pins. Terminals for current being sensed; fused internally, loop to IP+ pins; unidirectional or bidirectional current flow. |
| 13, 14, 23, 24 | NC | No connection |
| 15 | GND | Device ground connection. |
| 16 | VZCR | Voltage Reference Output pin. Zero current (0 A) reference; output voltage on this pin scales with V _{CC} . |
| 17 | FILTER | Filter pin. Terminal for an external capacitor connected from this pin to GND to set the device bandwidth. |
| 18 | VIOUT | Analog Output pin. Output voltage on this pin is proportional to current flowing through the loop between the IP+ pins and IP- pins. |
| 19 | FAULT | Overcurrent Fault pin. When current flowing between IP+ pins and IP- pins exceeds the overcurrent fault threshold, this pin transitions to a logic low state. |
| 20 | VCC | Supply voltage. |
| 21 | VOC | Overcurrent Input pin. Analog input voltage on this pin sets the overcurrent fault threshold. |
| 22 | FAULT_EN | Enables overcurrent faulting when high. Resets FAULT when low. |

COMMON OPERATING CHARACTERISTICS Valid at $T_A = -40^{\circ}\text{C}$ to 150°C , $V_{CC} = 5\text{ V}$, unless otherwise specified

¹Devices are trimmed for maximum accuracy at $V_{CC} = 5\text{ V}$. The ratiometry feature of the device allows operation over the full V_{CC} range; however, accuracy may be slightly degraded for V_{CC} values other than 5 V. Contact the Allegro factory for applications that require maximum accuracy for $V_{CC} = 3.3\text{ V}$.

² $R_{F(INT)}$ forms an RC circuit via the FILTER pin.

³This parameter can drift by as much as 0.25% over the lifetime of this product.

⁴This parameter can drift by as much as 0.3% over the lifetime of this product.

⁵Calculated using the formula $f_{3dB} = 0.35 / t_r$.

⁶See page 8 on how to set overcurrent fault switchpoint.

⁷Switchpoint can be lower at the expense of switchpoint accuracy.

⁸This error specification does not include the effect of noise. See the I_{NCOMP} specification in order to factor in the additional influence of noise on the fault switchpoint.

Setting Overcurrent Fault Switchpoint

The V_{OC} needed for setting the overcurrent fault switchpoint can be calculated as follows:

$$V_{OC} = \text{Sens} \times |I_{OC}| ,$$

where V_{OC} is in mV, Sens in mV/A, and I_{OC} (overcurrent fault switchpoint) in A.

$|I_{OC}|$ is the overcurrent fault switchpoint for a bi-directional (AC) current, which means a bi-directional device will have two symmetrical overcurrent fault switchpoints, $+I_{OC}$ and $-I_{OC}$.

See the following graph for I_{OC} and V_{OC} ranges.

Example: For ACS709LLFTR-35BB-T, if required overcurrent fault switchpoint is 50 A, and $V_{CC} = 5$ V, then the required V_{OC} can be calculated as follows:

$$V_{OC} = \text{Sens} \times I_{OC} = 28 \times 50 = 1400 \text{ (mV)}$$

Functional Description

Overcurrent Fault Operation

The primary concern with high-speed fault detection is that noise may cause false tripping. Various applications have or need to be able to ignore certain faults that are due to switching noise or other parasitic phenomena, which are application dependant. The problem with simply trying to filter out this noise up front is that in high-speed applications, with asymmetric noise, the act of filtering introduces an error into the measurement. To get around this issue, and allow the user to prevent the fault signal from being latched by noise, a circuit was designed to slew the $\overline{\text{FAULT}}$ pin voltage based on the value of the capacitor from that pin to ground. Once the voltage on the pin falls below 2 V, as established by an internal reference, the fault output is latched and pulled to ground quickly with an internal N-channel MOSFET.

Fault Walk-through

The following walk-through references various sections and attributes in the figure below. This figure shows different fault set/reset scenarios and how they relate to the voltages on the $\overline{\text{FAULT}}$ pin, FAULT_EN pin, and the internal Overcurrent (OC) Fault node, which is invisible to the customer.

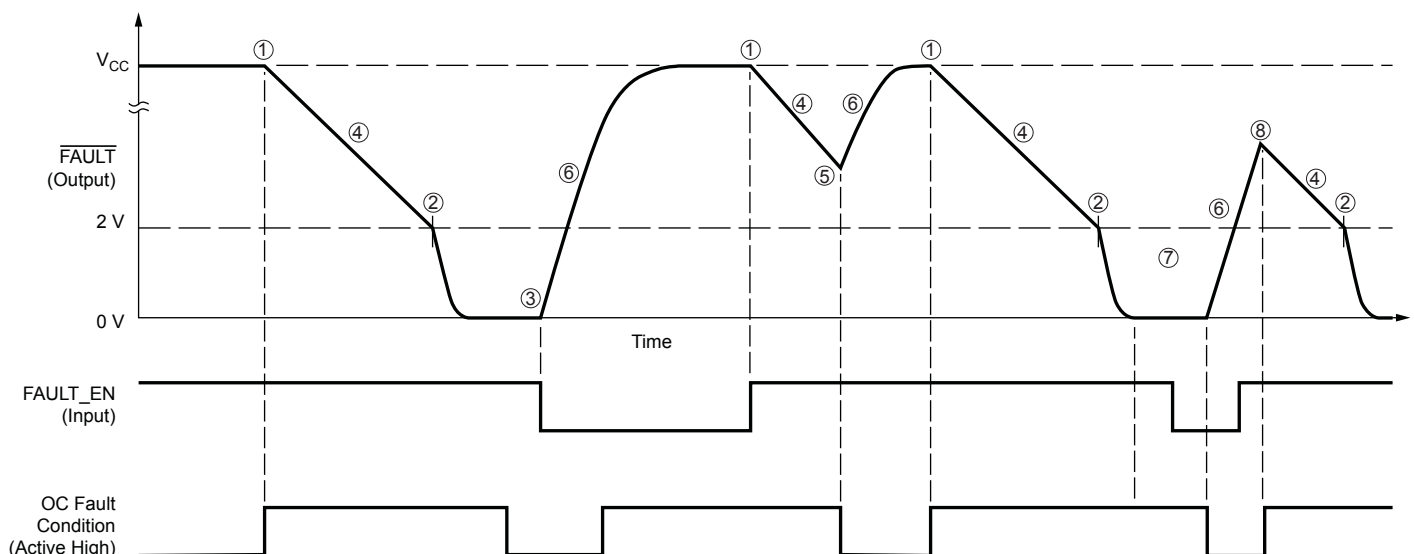

1. Because the device is enabled (FAULT_EN is high) and there is an OC fault condition, the device $\overline{\text{FAULT}}$ pin starts discharging.

- When the $\overline{\text{FAULT}}$ pin voltage reaches approximately 2 V, the fault is latched, and an internal NMOS device pulls the $\overline{\text{FAULT}}$ pin voltage to approximately 0 V. The rate at which the $\overline{\text{FAULT}}$ pin slews downward (see [4] in the figure) is dependent on the external capacitor, C_{OC} , on the $\overline{\text{FAULT}}$ pin.
- When the $\overline{\text{FAULT}}$ pin voltage reaches approximately 2 V, the fault is latched, and an internal NMOS device pulls the $\overline{\text{FAULT}}$ pin voltage to approximately 0 V. The rate at which the $\overline{\text{FAULT}}$ pin slews downward (see [4] in the figure) is dependent on the external capacitor, C_{OC} , on the $\overline{\text{FAULT}}$ pin.
- When the FAULT_EN pin is brought low, the $\overline{\text{FAULT}}$ pin starts resetting if no OC Fault condition exists. The internal NMOS pull-down turns off and an internal PMOS pull-up turns on (see [7] if the OC Fault condition still exists).
- The slope, and thus the delay, on the fault is controlled by the capacitor, C_{OC} , placed on the $\overline{\text{FAULT}}$ pin to ground. During this portion of the fault (when the $\overline{\text{FAULT}}$ pin is between V_{CC} and 2 V), there is a 3 mA constant current sink, which discharges C_{OC} . The length of the fault delay, t , is equal to:

$$t = \frac{C_{OC} \times (V_{CC} - 2 \text{ V})}{3 \text{ mA}} \quad (1)$$

where V_{CC} is the device power supply voltage.

- The $\overline{\text{FAULT}}$ pin did not reach the 2 V latch point before the OC fault condition cleared. Because of this, the fixed 3 mA current sink turns off, and the internal PMOS pull-up turns on to recharge C_{OC} through the $\overline{\text{FAULT}}$ pin.

6. This curve shows V_{CC} charging external capacitor C_{OC} through the internal PMOS pull-up. The slope is determined by C_{OC} .
7. When the $\overline{\text{FAULT_EN}}$ pin is brought low, if the fault condition still exists, the latched $\overline{\text{FAULT}}$ pin will stay low until the fault condition is removed, then it will start resetting.
8. At this point there is a fault condition, and the part is enabled before the $\overline{\text{FAULT}}$ pin can charge to V_{CC} . This shortens the user-set delay, so the fault is latched earlier. The new delay time can be calculated by equation 1, after substituting the voltage seen on the $\overline{\text{FAULT}}$ pin for V_{CC} .

Chopper Stabilization Technique

Chopper Stabilization is an innovative circuit technique that is used to minimize the offset voltage of a Hall element and an associated on-chip amplifier. Allegro patented a Chopper Stabilization technique that nearly eliminates Hall IC output drift induced by temperature or package stress effects. This offset reduction

technique is based on a signal modulation-demodulation process. Modulation is used to separate the undesired dc offset signal from the magnetically induced signal in the frequency domain. Then, using a low-pass filter, the modulated DC offset is suppressed while the magnetically induced signal passes through the filter. As a result of this chopper stabilization approach, the output voltage from the Hall IC is desensitized to the effects of temperature and mechanical stress. This technique produces devices that have an extremely stable Electrical Offset Voltage, are immune to thermal stress, and have precise recoverability after temperature cycling.

This technique is made possible through the use of a BiCMOS process that allows the use of low-offset and low-noise amplifiers in combination with high-density logic integration and sample and hold circuits.

Concept of Chopper Stabilization Technique

Definitions of Accuracy Characteristics

Sensitivity (Sens). The change in device output in response to a 1 A change through the primary conductor. The sensitivity is the product of the magnetic circuit sensitivity (G/A) and the linear IC amplifier gain (mV/G). The linear IC amplifier gain is programmed at the factory to optimize the sensitivity (mV/A) for the full-scale current of the device.

Noise (V_{NOISE}). The product of the linear IC amplifier gain (mV/G) and the noise floor for the Allegro Hall effect linear IC (≈ 1 G). The noise floor is derived from the thermal and shot noise observed in Hall elements. Dividing the noise (mV) by the sensitivity (mV/A) provides the smallest current that the device is able to resolve.

Linearity (E_{LIN}). The degree to which the voltage output from the device varies in direct proportion to the primary current through its full-scale amplitude. Nonlinearity in the output can be attributed to the saturation of the flux concentrator approaching the full-scale current. The following equation is used to derive the linearity:

$$100 \left\{ 1 - \left[\frac{V_{IOUT_full\text{-}scale\text{ amperes}} - V_{IOUT(Q)}}{2 (V_{IOUT_1/2\text{ full-scale amperes}} - V_{IOUT(Q)})} \right] \right\}$$

where $V_{IOUT_full\text{-}scale\text{ amperes}}$ = the output voltage (V) when the sensed current approximates full-scale $\pm I_p$.

Symmetry (E_{SYM}). The degree to which the absolute voltage output from the device varies in proportion to either a positive or negative full-scale primary current. The following formula is used to derive symmetry:

$$100 \left(\frac{V_{IOUT_+full\text{-}scale\text{ amperes}} - V_{IOUT(Q)}}{V_{IOUT(Q)} - V_{IOUT_full\text{-}scale\text{ amperes}}} \right)$$

Quiescent output voltage (V_{IOUT(Q)}). The output of the device when the primary current is zero. For a unipolar supply voltage, it nominally remains at $0.5 \times V_{CC}$. For example, in the case of a bidirectional output device, $V_{CC} = 5$ V translates into $V_{IOUT(Q)} = 2.5$ V. Variation in $V_{IOUT(Q)}$ can be attributed to the resolution of the Allegro linear IC quiescent voltage trim and thermal drift.

Electrical offset voltage (V_{OE}). The deviation of the device output from its ideal quiescent voltage due to nonmagnetic causes. To convert this voltage to amperes, divide by the device sensitivity, Sens.

Accuracy (E_{TOT}). The accuracy represents the maximum deviation of the actual output from its ideal value. This is also known as the total output error. The accuracy is illustrated graphically in the output voltage versus current chart at right. Note that error is directly measured during final test at Allegro.

Accuracy is divided into four areas:

- **0 A at 25°C.** Accuracy of sensing zero current flow at 25°C, without the effects of temperature.
- **0 A over Δ temperature.** Accuracy of sensing zero current flow including temperature effects.
- **Full-scale current at 25°C.** Accuracy of sensing the full-scale current at 25°C, without the effects of temperature.
- **Full-scale current over Δ temperature.** Accuracy of sensing full-scale current flow including temperature effects.

Ratiometry. The ratiometric feature means that its 0 A output, $V_{IOUT(Q)}$, (nominally equal to $V_{CC}/2$) and sensitivity, Sens, are proportional to its supply voltage, V_{CC} . The following formula is used to derive the ratiometric change in 0 A output voltage, $\Delta V_{IOUT(Q)RAT}$ (%).

$$100 \left(\frac{V_{IOUT(Q)VCC} / V_{IOUT(Q)5V}}{V_{CC} / 5V} \right)$$

The ratiometric change in sensitivity, $\Delta Sens_{RAT}$ (%), is defined as:

$$100 \left(\frac{Sens_{VCC} / Sens_{5V}}{V_{CC} / 5V} \right)$$

Accuracy at 0 A and at Full-Scale Current

Definitions of Dynamic Response Characteristics

Propagation delay (t_{PROP}). The time required for the device output to reflect a change in the primary current signal. Propagation delay is attributed to inductive loading within the linear IC package, as well as in the inductive loop formed by the primary conductor geometry. Propagation delay can be considered as a fixed time offset and may be compensated.

Response time ($t_{RESPONSE}$). The time interval between a) when the primary current signal reaches 90% of its final value, and b) when the device reaches 90% of its output corresponding to the applied current.

Rise time (t_r). The time interval between a) when the device reaches 10% of its full scale value, and b) when it reaches 90% of its full scale value. The rise time to a step response is used to derive the bandwidth of the current sensor IC, in which $f(-3 \text{ dB}) = 0.35/t_r$. Both t_r and $t_{RESPONSE}$ are detrimentally affected by eddy current losses observed in the conductive IC ground plane.

Package LF, 24-pin QSOP
