TDA1311A Stereo Continuous Calibration DAC (CC-DAC)

Preliminary specification
Supersedes data of July 1993
File under Integrated Circuits, IC01

1995 Dec 18

Stereo Continuous Calibration DAC (CC-DAC)

TDA1311A

FEATURES

- Voltage output
- Space saving packages SO8 or DIP8
- Low power consumption
- Wide dynamic range (16-bit resolution)
- Continuous Calibration (CC) concept
- Easy application:
 - single 4 to 5.5 V rail supply
 - output current and bias current are proportional to the supply voltage
 - integrated current-to-voltage converter
- Fast settling time permits 2, 4 and 8 × oversampling (serial input) or double-speed operation at 4 × oversampling
- Internal bias current ensures maximum dynamic range
- Wide operating temperature range (−40 °C to +85 °C)
- Compatible with most current Japanese input formats: time multiplexed, two's complement, TTL
- No zero-crossing distortion
- Cost efficient.

GENERAL DESCRIPTION

The TDA1311A; AT is a voltage-driven digital-to-analog converter and is new generation of DAC devices which embodies the innovative technique of Continuous Calibration (CC). The largest bit-currents are repeatedly generated by one single current reference source. This duplication is based upon an internal charge storage principle which has an accuracy insensitive to ageing, temperature matching and process variations.

The TDA1311A; AT is fabricated in a 1.0 μm CMOS process and features an extremely low-power dissipation, small package size and easy application. Furthermore, the accuracy of the intrinsic high coarse-current combined with the implemented symmetrical offset decoding method preclude zero-crossing distortion and ensures high quality audio reproduction. Therefore, the CC-DAC is eminently suitable for use in (portable) digital audio equipment.

ORDERING INFORMATION

TYPE NUMBER	PACKAGE		
	NAME	DESCRIPTION	VERSION
TDA1311A	DIP8	plastic dual in-line package; 8 leads (300 mil)	SOT97-1
TDA1311AT	SO8	plastic small outline package; 8 leads; body width 3.9 mm	SOT96-1

Stereo Continuous Calibration DAC (CC-DAC)

TDA1311A

FUNCTIONAL DESCRIPTION

The basic operation of the continuous calibration DAC is illustrated in Fig.3. The figure shows the calibration and operation cycle. During calibration of the MOS current source (see Fig.3a) transistor M1 is connected as a diode by applying a reference current. The voltage V_{gs} on the intrinsic gate-source capacitance C_{gs} of M1 is then determined by the transistor characteristics. After calibration of the drain current to the reference value I_{REF} , the switch S1 is opened and S2 is switched to the other position (see Fig.3b). The gate-to-source voltage V_{gs} of M1 is not changed because the charge on C_{gs} is preserved. Therefore, the drain current of M1 will still be equal to I_{REF} and this exact duplicate of I_{REF} is now available at the OUT terminal.

The 32 current sources and the spare current source of the TDA1311A; AT are continuously calibrated (see Fig.1). The spare current source is included to allow continuous converter operation. The output of one calibrated source is connected to an 11-bit binary current divider consisting of 2048 transistors.

A symmetrical offset decoding principle is incorporated that arranges the bit switching in such a way that the zero-crossing is performed only by switching the LSB currents.

The TDA1311A; AT (CC-DAC) accepts serial input data formats of 16-bit word length. Left and right data words are time multiplexed. The most significant bit (bit 1) must always be first. The input data format is shown in Figs 4 and 5.

With a HIGH level on the word select input (WS), data is placed in the left input register and with a LOW level on the WS input, data is placed in the right input register (see Fig.1). The data in the input registers are simultaneously latched in the output registers which control the bit switches.

An internal offset voltage V_{OS} is added to the full scale output voltage V_{FS} ; V_{OS} and V_{FS} are proportional to V_{DD} : $V_{DD1}/V_{DD2} = V_{FS1}/V_{FS2} = V_{OS1}/V_{OS2}$.

APPLICATION INFORMATION

Basic application example

A typical example of a CD-application with the TDA1311A; AT is shown in Fig.6. It features typical decoupling components and a third-order analog post-filter stage providing a line output.

Fig.6 Example of a 3rd order filter application.

Attention to printed circuit board layout

The TDA1311A and even more so the TDA1311AT offers great ease in designing-in to printed-circuit boards due to its small size and low pin count. The TDA1311A; AT being a mixed-signal IC in CMOS, some attention needs to be paid to layout and topology of the application PCB. Following some basic rules will yield the desired performance. The most important considerations are:

1. Supply: care should be taken to supply the TDA1311A; AT with a clean, noiseless V_{DD} , for a good noise performance of the analog parts of the DAC. Supply purity can easily be achieved by using an RC-filtered supply.
2. Grounding: preferably a ground plane should be used, in order to have a low-impedance return available at any point in the layout. It is advantageous to make a partitioning of the ground plane according to the nature of the expected return currents (digital input returns separate from supply returns and separate from the analog section).

3. Topology: the capacitor decoupling high-frequency supply interference from V_{DD} to GND should be placed as close as is physically possible to the IC body, ensuring a low-inductance path to ground. The digital input conductors may be shielded by ground leads running alongside. The placement of a passive ground plane underside the entire IC surface gives 'free' additional decoupling from the IC body to ground as well as providing a shield between the digital input pins and the analog output pins.

Figure 7 shows recommended layouts for printed-circuit boards for the SO8 and DIL8 versions respectively. Both layouts use a single-interconnect layer.

Evaluation of audio parameters

The following measurement graphs are performed on singular engineering samples; therefore **no** guarantee of typical parameter values is implied. Measurement conditions are typical, as stated in the section Characteristics, unless otherwise indicated. The normal measurement set-up includes a 20 kHz band-limiting filter for bandwidth definition, and an A-weighting filter where indicated.

SOLDERING

Introduction

There is no soldering method that is ideal for all IC packages. Wave soldering is often preferred when through-hole and surface mounted components are mixed on one printed-circuit board. However, wave soldering is not always suitable for surface mounted ICs, or for printed-circuits with high population densities. In these situations reflow soldering is often used.

This text gives a very brief insight to a complex technology. A more in-depth account of soldering ICs can be found in our *"IC Package Databook"* (order code 9398 652 90011).

DIP

SOLDERING BY DIPPING OR BY WAVE

The maximum permissible temperature of the solder is 260 °C; solder at this temperature must not be in contact with the joint for more than 5 seconds. The total contact time of successive solder waves must not exceed 5 seconds.

The device may be mounted up to the seating plane, but the temperature of the plastic body must not exceed the specified maximum storage temperature ($T_{stg\ max}$). If the printed-circuit board has been pre-heated, forced cooling may be necessary immediately after soldering to keep the temperature within the permissible limit.

REPAIRING SOLDERED JOINTS

Apply a low voltage soldering iron (less than 24 V) to the lead(s) of the package, below the seating plane or not more than 2 mm above it. If the temperature of the soldering iron bit is less than 300 °C it may remain in contact for up to 10 seconds. If the bit temperature is between 300 and 400 °C, contact may be up to 5 seconds.

SO

REFLOW SOLDERING

Reflow soldering techniques are suitable for all SO packages.

Reflow soldering requires solder paste (a suspension of fine solder particles, flux and binding agent) to be applied to the printed-circuit board by screen printing, stencilling or pressure-syringe dispensing before package placement.

Several techniques exist for reflowing; for example, thermal conduction by heated belt. Dwell times vary between 50 and 300 seconds depending on heating method. Typical reflow temperatures range from 215 to 250 °C.

Preheating is necessary to dry the paste and evaporate the binding agent. Preheating duration: 45 minutes at 45 °C.

WAVE SOLDERING

Wave soldering techniques can be used for all SO packages if the following conditions are observed:

- A double-wave (a turbulent wave with high upward pressure followed by a smooth laminar wave) soldering technique should be used.
- The longitudinal axis of the package footprint must be parallel to the solder flow.
- The package footprint must incorporate solder thieves at the downstream end.

During placement and before soldering, the package must be fixed with a droplet of adhesive. The adhesive can be applied by screen printing, pin transfer or syringe dispensing. The package can be soldered after the adhesive is cured.

Maximum permissible solder temperature is 260 °C, and maximum duration of package immersion in solder is 10 seconds, if cooled to less than 150 °C within 6 seconds. Typical dwell time is 4 seconds at 250 °C.

A mildly-activated flux will eliminate the need for removal of corrosive residues in most applications.

REPAIRING SOLDERED JOINTS

Fix the component by first soldering two diagonally-opposite end leads. Use only a low voltage soldering iron (less than 24 V) applied to the flat part of the lead. Contact time must be limited to 10 seconds at up to 300 °C. When using a dedicated tool, all other leads can be soldered in one operation within 2 to 5 seconds between 270 and 320 °C.

TDA1311A

DEFINITIONS

Data sheet status	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
Limiting values	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
Application information	
Where application information is given, it is advisory and does not form part of the specification.	

LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.
